

Assessment plan of course 4RC30

Group assignment is to solve a self-defined flow problem in groups of 2 or 3 persons and then write out a paper.

- Students form the group on their own.
- Students will define the problem based on their own interest, which involves **at least two components** of
 - heat transfer
 - chemical reaction
 - turbulence
- The flow problem needs to be approved by the teacher (Niels or Yali).
- To solve the problem, student can either use the Matlab code supplied in the course or write their own code. Any commercial software or open-source packages are not allowed.
- The paper should be written in the format of the supplied template and submitted before the given deadline.
- After paper submission, complete the Group Member Evaluation, which will be the inputs for individual assessment.

Assessment

The final grade is based on a group grade (80%) and an individual grade (20%):

- The group grade is based on the assessment of the report/paper by one of the teachers. The assessment utilizes a detailed rubric which covers components of problem description and analysis (15%), CFD model definition and execution (45%), results and analysis (25%), and writing (15%).
- The individual grade is based on the assessment (by the teacher) on students' individual contribution (CRediT authorship at end of the report/paper) and the peer evaluation from other group members. The group member evaluation is done using FeedbackFruits: Students will reflect on the collaborating and contributing process within groups as well as individual CFD skills developed within this course (with a rubric defined by the teacher).
- A minimum of 6 for the final grade (with a conditional grade ≥ 5.5 for individual assessment) is required to pass the course.

Retake opportunities are:

- To refine and improve the paper based on the feedback from the lecturers.
- To redo the entire final assignment.
